February 27, 2019

GENOVA DIAGNOSTICS®

# Objectives for This Presentation

- Gain a basic understanding on the pathophysiology of mild cognitive decline and Alzheimer's and how it relates to insulin resistance and the menopausal transition in women
- Review the potential mechanisms of diabetes type 2 and how it contributes to Alzheimer's disease in women
- Identify the hallmarks of hormone replacement with respect to Alzheimer's disease in women

- This study demonstrated that, in early midlife, women outperformed age-matched men across all memory measures, but sex differences were attenuated for postmenopausal women
- Initial learning and memory retrieval were particularly vulnerable, whereas memory consolidation and storage were preserved
- Findings underscore the significance of the decline in ovarian estradiol production in midlife and its role in shaping memory function

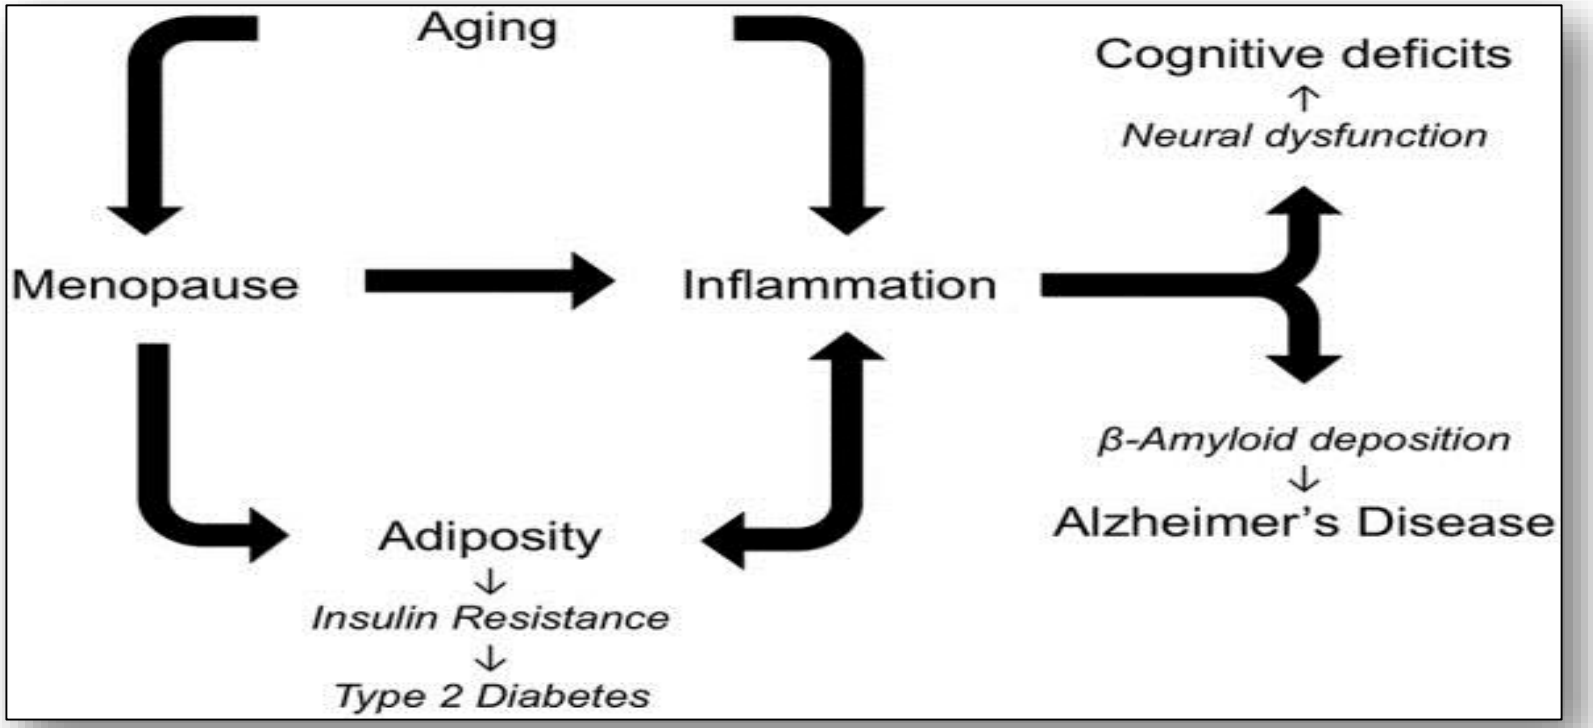
links to the disease, Aβ acc
pathogenesis (Hardy and Hig
an essential role of tau, which undergoes hyperphosphorylation resulting in the formation of neurofibrillary tangles, a hallmark of AD neuropathology found in many dead and dying neurons (Iqbal et al., 2010). Emerging evidence indicates that tau, like Aβ, can be a potent pathogenic protein and that it is capable of spreading pathology in a prion-like manner (Bloom, 2014; Zempel and Mandelkow, 2014).

AD is more than just the accumulation of oligomeric and fibrillar Aβ and abnormally phosphorylated tau. The disease is characterized by many pathologic changes, including hypometabolism (Mosconi et al., 2008; Yao et al., 2011), blood-brain-barrier (BBB) disruption (Zlokovic, 2011), and glial activation (Mrak and Griffin, 2005; Prokop et al., 2013). Sporadic AD, which is not driven by the genetic mutations in familial AD and represents the vast majority of cases, is likely to reflect the interactive effects of normal aging with numerous environmental risk factors and subtle genetic polymorphisms. In turn, these

"The onset of menopause in mid-life elevates the vulnerability of women to AD, an increased risk that is likely associated with the depletion of estrogens. Menopause is also linked with an abundance of additional changes, including increased central adiposity and inflammation."

GENOVA DIAGNOSTICS

Christensen A, et al. *Front Aging Neurosci*. 2015;7:130.



**"Alzheimer's disease (AD) is a multifactorial disorder in which multiple risk factors are theorized to interact in regulating pathogenesis.** As depicted in the diagram an essential factor in AD is increasing age, which is also associated with elevated inflammation and, in women, menopause. The loss of estrogens at menopause increases central adiposity, which in turn increases inflammation and predisposes women to metabolic syndrome, insulin resistance, and AD. Individually and cooperatively, aging, menopause, adiposity, and inflammation lead to cognitive deficits and AD."

**While a potential causal factor in Alzheimer's disease (AD), brain insulin resistance has not been demonstrated directly in that disorder. We provide such a demonstration here by showing that the hippocampal formation (HF) and, to a lesser degree, the cerebellar cortex in AD cases without diabetes exhibit markedly reduced responses to insulin signaling in the IR→IRS-1→PI3K signaling pathway with greatly reduced responses to IGF-1 in the IGF-1R→IRS-2→PI3K signaling pathway. Reduced insulin responses were maximal at the level of IRS-1 and were consistently associated with basal elevations in IRS-1 phosphorylated at serine 616 (IRS-1 pS$^{616}$) and IRS-1 pS$^{636/639}$. In the HF, these candidate biomarkers of brain insulin resistance increased commonly and progressively from normal cases to mild cognitively impaired cas… APOE ε4 status. ## Introduction

Alzheimer's disease (AD) shares many age-related pathophysiological features of type 2 diabetes (T2D). These include the defining features of T2D, insulin resistance and disrupted glucose metabolism in non-neural tissues (1, 2), as well as peripheral oxidative and inflammatory stress, amyloid aggregation, neural atrophy and/or degeneration, and cognitive decline (3, 4). Such a large set of shared features suggests shared etiologies, a view supported by epidemiologic studies showing that AD risk is increased 50%–100% by diabetes (5–8), including T2D (9), which accounts for 90% of all diabetic cases (10).

Of the shared features of AD and T2D, the one most likely to be an etiological factor in AD is insulin resistance, defined broadly here as reduced cellular responsiveness to insulin, in keeping with Goldstein's description (1). This factor is not only associated with, but can cause, many shared features of the 2 disorders (3, 4, 11–13). Moreover, peripheral insulin resistance without T2D is a risk factor for AD (8, 14) within 3 years of diagnosis (14); is a common feature of AD cases (15); and is associated with reduced basal (16) and insulin-induced (17, 18) activation of cerebral IRs, higher cerebral neu…

12, 26–35). This is consistent with observed alterations in levels of many insulin signaling molecules in the forebrain of AD cases (27–29, 33, 35–37) and with memory improvements in such cases and those at high risk for AD after selective elevation of forebrain insulin via intranasal administration of the hormone (38, 39).

While insulin activates several signaling pathways (40), the logical starting point for studies on brain insulin resistance has been the signaling pathway commonly disrupted under conditions causing peripheral insulin resistance, including T2D and obesity. As diagrammed in Supplemental Figure 1 (supplemental material available online with this article; doi:10.1172/JCI59903DS1), the upstream portion of that pathway uses the following activation sequence: IR→IRS-1/2→PI3K→Akt (the last of which is also

**Background:** Mild cognitive impairment (MCI) is the prodromal stage of Alzheimer's disease (AD), so identification of the related risk factors can be helpful. Although the association between type 2 diabetes mellitus (T2DM) and these modest changes in cognition is well established, whether T2DM will promote the transformation of MCI into AD is not a unified conclusion.

**Objective:** This study aims to explore the relationship between T2DM and MCI in the elderly population living in the community in Shanghai, People's Republic of China.

**Methods:** A total of 197 participants were included in the study. They were screened for T2DM, hyperlipidemia, traumatic brain injury, and family history of dementia. The Mini-Mental State Examination and the Montreal Cognitive Assessment were used to assess cognitive function. The diagnosis of AD was made according to *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*, whereas the diagnosis of MCI was made according to Petersen's criteria. Then, we investigated the relation between T2DM and MCI.

**Results:** A total of 82 (41.6%) participants had no cognitive impairment, 82 (41.6%) participants

sion models

95% CI =21.

**Conclusion**

## Introduction

Alzheimer's disease (AD) is a progressive neurodegenerative disorder and the most common form of dementia among the population aged >65 years.[1] It is characterized by extracellular amyloid plaques and neurofibrillary tangles.[2] Mild cognitive impairment (MCI) is often considered to be a transitional phase between healthy cognitive aging and AD.[3] Up to 60% of MCI patients will develop AD within a 10-year period, but many people can remain cognitively stable or regain normal cognitive function.[4] There are many factors that affect the progress of MCI, for example, sex difference.[5] Type 2 diabetes mellitus (T2DM) might also be a potential risk for MCI progressing into AD, by inducing vascular dysfunction and oxidative and inflammatory stress.[6] Many cognitive functions, such as learning and memory, mental flexibility, and mental speed, have also been proved to be impaired in patients with T2DM.[7] Some epidemiological studies demonstrated that T2DM was a risk factor for developing cognitive impairment and dementia, including AD.[8,9] Also, a prospective longitudinal study conducted in the southeastern region of Singapore showed that T2DM was associated with an increased incidence of MCI and progression to dementia.[10] However, Leibson et al[11]

REVIEW ARTICLE

# Alzheimer's Disease Is Type 3 Diabetes—Evidence Reviewed

Suzanne M. de la Monte, M.D., M.P.H.[1–3] and Jack R. Wands, M.D.[3]

**Abstract**

Alzheimer's disease (AD) has characteristic histopathological, molecular, and biochemical abnormalities, including cell loss; abundant neurofibrillary tangles; dystrophic neurites; amyloid precursor protein, amyloid-β (APP-Aβ) deposits; increased activation of prodeath genes and signaling pathways; impaired energy metabolism; mitochondrial dysfunction; chronic oxidative stress; and DNA damage. Gaining a better understanding of AD pathogenesis will require a framework that mechanistically interlinks all these phenomena. Currently, there is a rapid growth in the literature pointing toward insulin deficiency and insulin resistance as mediators of AD-type neurodegeneration, but this surge of new information is riddled with conflicting and unresolved concepts regarding the potential contributions of type 2 diabetes mellitus (T2DM), metabolic syndrome, and obesity to AD pathogenesis. Herein, we review

# Type 3 Diabetes: Cross Talk between Differentially Regulated Proteins of Type 2 Diabetes Mellitus and Alzheimer's Disease

Received: 22 October 2015
Accepted: 15 April 2016
Published: 06 May 2016

Khyati Mittal*, Ruchi Jakhmola Mani* & Deepshikha Pande Katare

**Type 3 Diabetes (T3D) is a neuroendocrine disorder that represents the progression of Type 2 Diabetes Mellitus (T2DM) to Alzheimer's disease (AD). T3D contributes in the increase of the total load of Alzheimer's patients worldwide. The protein network based strategies were used for the analysis of protein interactions and hypothesis was derived describing the possible routes of communications among proteins. The hypothesis provides the insight on the probable mechanism of the disease progression for T3D. The current study also suggests that insulin degrading enzyme (IDE) could be the major player which holds the capacity to shift T2DM to T3D by altering metabolic pathways like regulation of beta-cell development, negative regulation of PI3K/AKT pathways and amyloid beta degradation.**

Insulin signaling pathways are conserve
homeostasis and reproduction in living
ent at the blood brain barrier. It is propo
hippocampal region of brain. It stimula
enhancing the glucose uptake in the ti
similar in both peripheral tissue and hi
molecular mechanisms involved in the p
ings suggest that both beta cells and neu
sensitive potassium channels in similar
nerve endings in rat brain and was released under depolarization conditions[2]. The study also suggests that insulin secretion in synaptosomes is increased by glucose and addition of glycolytic inhibitor resulted in 50% decrease in glucose-induced release of immunoreactive insulin[2]. Hence the process of glucose metabolism is similar in brain and pancreas and the brain itself might synthesize some portion of the insulin[2].

The binding of insulin to its receptor leads to cascades of intracellular signaling which activates the Insulin Receptor Substrate-1(IRS1), extracellular signal-related kinase/mitogen -activated protein kinase (ERK/MAPK), and PI3kinase/AKT pathways (PI3K/AKT) followed by inhibition or suppression of glycogen synthase kinase-3 (GSK-3)[2]. Disturbances to these pathways can lead to complication like cardiovascular diseases, pancreatic cancer, neuropathy, nephropathy etc[2]. It also adds to several other issues like mitochondrial dysfunction, oxidative stress and dysregulated metabolic profiles[2].

There is an exponential increase in the prevalence of T2DM cases worldwide and it is likely to reach 592 million by 2035[3]. Also the incidences of T2DM induced AD is rapidly increasing in human population in last few years[4]. T2DM patients have almost double the chances of developing AD in comparison to the patients that have only insulin resistance[5]. Therefore, T3D is also adding to the already existing burden of AD in the society.

T2DM and AD patients have similar amyloid beta deposits both in pancreas as in the brain[6]. Several researchers have suggested this new pathology to be addressed as Type 3 Diabetes (T3D)[4–7]. Some of the target receptors of T2DM such as IGF-1R, PPARG and IDE are also involved in the regulation of the expression and phosphorylation of tau protein[7]. It is intriguing to observe that both hyperinsulinaemia and IDE are related to the risk of AD

**Alzheimer's disease: review of hormone therapy trials and implications for treatment and prevention after menopause**

**Victor W. Henderson, MD, MS**
Departments of Health Research & Policy (Epidemiology) and of Neurology & Neurological Sciences, Stanford University, Stanford, CA

**Abstract**

Hormonal changes associated with the menopausal transition and postmenopause have the potential to influence processes linked to Alzheimer's disease symptoms and pathogenesis, but effects of menopause on Alzheimer risk can be addressed only indirectly. Nine randomized clinical trials of estrogen-containing hormone therapy in Alzheimer's disease patients were identified by a systematic literature search. Findings suggest that hormone therapy does not improve cognitive symptoms of women with Alzheimer's disease. No clinical trials of hormone therapy address Alzheimer prevention, but one clinical trial provides moderate evidence that continuous, combined estrogen plus progestogen initiated at age 65 years or older increases the risk of dementia. The timing, or critical window, hyp
initiated at a younger age in closer temporal proximit

SHORT REVIEW

# Alzheimer's disease, menopause and the impact of the estrogenic environment

A. Pines

Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel

**ABSTRACT**

Decades ago, postmenopausal hormone replacement was considered the panacea for midlife women. Prevention of the age-related cognitive decline was among the top alleged benefits of this therapy. However, the data from the Women's Health Initiative Memory Study (WHI-WHIMS) study showed the opposite, indicating worsening of several cognitive domains in hormone users. Since WHIMS recruited women who were 65 years or older, it became crucial to investigate the effects of hormone therapy in the early menopause as well. Recent studies, such as WHIMS-Young, the Kronos Early Estrogen Prevention Study and the Early versus Late Intervention Trial with Estradiol targeted the younger women, and indeed showed that hormone therapy may have positive cognitive outcomes in this age group. Whether or not hormone therapy has an effect on already demented women remains to be further explored, as data are scarce.

Alzheimer's disease; cognition; menopause; postmenopausal hormone therapy

Alzheimer's disease (AD), a chronic neurocognitive illness of old age, is one of the most challenging targets for medicine in the 21st century[1]. Its personal, familial, social and economic burden has become very significant in view of the constant prolongation of life expectancy and the increasing percent of elderly people in the general population. Many resea resources are invested in identifying people at higher risk AD and ways to reduce such risk, on the one hand, development of effective medications to treat AD, on other hand. It is now understood that the pathophysiolog mechanisms are complex and include various age-rela protective, and disease-promoting factors which may inte with the traditional core theory of amyloid and tau prote New data keep piling up constantly, including data on ger differences.

AD is more prevalent in women, who have two- greater lifetime risk of developing AD compared to m This sex difference in incidence raises questions on potential contribution of menopause-related hormo deficiencies and addresses issues specific to women. example, the apolipoprotein E (apoE) ε4 allele is an est lished genetic risk factor for AD; 40–65% of AD patie have at least one copy of the ε4 allele and those with ε4 alleles have up to 20 times the risk of developing In healthy, elderly controls only 15% carry this variant the central nervous system, apoE transports cholesterol the neurons via apoE receptors and is involved in amy deposition. apoE ε4 affects the probability of develop AD more in women than in men. Furthermore, this com- mon polymorphism increases the risk of clinical conversion more in women than in men, both in the conversion from healthy cognitive aging to minimal cognitive impairment and in the conversion from minimal cognitive impairment to AD.

The Early versus Late Intervention Trial with Estradiol (ELITE) investigated risk parameters for cognitive decline in healthy postmenopausal women[3]. ELITE was a double-blinded, placebo–controlled, clinical trial randomizing 643

lower executive, global and memory cognitive performance. A general improvement in cognitive performance was observed in women randomized to HT. Women in all three metabolic phenotypes showed significant increases in global cognition (all $p < 0.05$), and women in the healthy and high blood pressure phenotypes had a significant increase in

"Sex hormones, particularly estrogens possess potent antioxidant properties and play important roles in maintaining normal reproductive and non-reproductive functions. They exert neuroprotective actions and their loss during aging and natural or surgical menopause is associated with mitochondrial dysfunction, neuroinflammation, synaptic decline, cognitive impairment and increased risk of age-related disorders. Moreover, loss of sex hormones has been suggested to promote an accelerated aging phenotype eventually leading to the development of brain hypometabolism, a feature often observed in menopausal women and prodromal Alzheimer's disease (AD)."

Preclinical studies identified the perimenopause t
transition state unique to the female, as a sex-spe
genic regulation of cerebral glucose metabolism (
This is evident in glucose hypometabolism and de
sustained thereafter. This study bridges basic to c
ergetics in a cohort of forty-three, 40–60 year-old
different endocrine transition stages including pre
menopause (PERI, n = 14) and postmenopause (
clinical, laboratory and neuropsychological exam
Positron Emission Tomography (PET) FDG-PET
mitochondrial cytochrome oxidase (COX) activity measures. Statistical parametric mapping and multiple regression models were used to examine clinical, CMRglc and COX data across groups. As expected, the MENO group was older than PERI and controls. Groups were otherwise comparable for clinical measures and distribution of APOE4 genotype. Both MENO and PERI groups exhibited reduced CMRglc in AD-vulnerable regions which was correlated with decline in mitochondrial COX activity compared to CNT ($p's<0.001$). A gradient in biomarker abnormalities was most pronounced in MENO, intermediate in PERI, and lowest in CNT ($p<0.001$). Biomarkers correlated with immediate and delayed memory scores (Pearson's $0.26 \leq r \leq 0.32$, $p \leq 0.05$). These findings validate earlier preclinical findings and indicate emergence of bioenergetic deficits in perimenopausal and postmenopausal women,

"…the optimal window of opportunity for therapeutic intervention in women is early in the endocrine aging process."

# Menopausal Complaints Are Associated With Cardiovascular Risk Factors

Gerrie-Cor M. Gast, Diederick E. Grobbee, Victor J.M. Pop, Jules J. Keyzer,
Colette J.M. Wijnands-van Gent, Göran N. Samsioe, Peter M. Nilsson, Yvonne T. van der Schouw

***Abstract***—It has been hypothesized that women with vasomotor symptoms differ from those without with respect to cardiovascular risk factors or responses to exogenous hormone therapy. We studied whether the presence and extent of menopausal complaints are associated with cardiovascular risk profile. Data were used from a population-based sample of 5523 women, aged 46 to 57 years, enrolled between 1994 and 1995. Data on menopausal complaints and potential confounders were collected by questionnaires. Total cholesterol, systolic and diastolic blood pressures, and body mass index were measured. Linear and logistic regression analyses were used to analyze the data. Night sweats were reported by 38% and flushing by 39% of women. After multivariate adjustment, women with complaints of flushing had a 0.27-mmol/L (95% CI: 0.15 to 0.39) higher cholesterol level, a 0.60-kg/m$^2$ (95% CI: 0.35 to 0.84) higher BMI, a 1.59-mm Hg (95% CI: 0.52 to 2.67) higher systolic blood pressure, and a 1.09-mm Hg (95% CI: 0.48 to 1.69) higher diastolic blood pressure compared with asymptomatic women. Flushing was also associated with hypercholesterolemia (odds ratio: 1.52; 95% CI: 1.25 to 1.84) and hypertension (OR: 1.20; 95% CI: 1.07 to 1.34). Results were similar for complaints of night sweating. The findings support the view that menopausal complaints are associated with a less favorable cardiovascular risk profile. These findings substantiate the view that differences in the presence of menopausal symptoms as a reason for using hormone therapy could explain discrepant findings between observational research and trials. (***Hypertension***. **2008;51:1492-1498.)**

**Key Words:** menopausal complaints ■ cholesterol ■ blood pressure ■ body mass index ■ cardiovascular risk profile ■ women

A number of observational studies demonstrated a protective association between hormone therapy (HT) and cardiovascular disease (CVD).[1–3] Placebo-controlled, randomized trials, however, could not confirm a cardioprotective effect and showed no overall benefit of HT on the risk of cardiovascular events.[4,5]

Many potential reasons have been proposed to explain this apparent discrepancy between the observational studies and the trials. An important difference is that, in the observational studies, the most common reason to initiate HT was to relieve menopausal complaints. In contrast, in the trials, women with severe complaints were either excluded or composed only a minority of the total randomized population. Results of a recent subgroup analysis of the combined Women's Health Initiative trials showed that women who initiated HT closer to menopause had a reduced coronary heart disease (CHD) risk compared with the increase in CHD risk among women initiating HT more distant from menopause.[6] Moreover, among women 50 to 59 years old at enrollment in the Women's Health Initiative, end-of-trial coronary calcium scores were lower in women assigned to estrogens than in those assigned to placebo.[7] A younger age is likely to

# Vasomotor symptoms and the homeostatic model assessment of insulin-resistance in Korean postmenopausal women

Dae Hui Kwon[1], Ju Hak Lee[1], Ki-Jin Ryu[2], Hyun-Tae Park[1], Tak Kim[1]

[1]Department of Obstetrics and Gynecology, Korea University Medical Center, Korea University College of Medicine, Seoul; [2]Ulleung-gun County Hospital, Ulleung, Korea

The aim of this cross-sectional study was to evaluate the association between vasomotor symptoms (VMS) and insulin resistance, which can be postulated by the homeostatic model assessment (HOMA) index. This study involved 1,547 Korean postmenopausal women (age, 45 to 65 years) attending a routine health check-up at a single institution in Korea from January 2010 to December 2012. A menopause rating scale questionnaire was used to assess the severity of VMS. The mean age of participants was 55.22±4.8 years and 885 (57.2%) reported VMS in some degree. The mean HOMA index was 1.79±0.96, and the HOMA index increased with an increase in severity of VMS (none, mild, moderate and severe) in logistic regression analysis (β=0.068, t=2.665, *P*=0.008). Insulin resistance needs to be considered to understand the linkage between VMS and cardiometabolic disorders.

Keywords: Homeostatic model assessment index; Hot flush; Insulin resistance; Menopause; Vasomotor symptoms

## Introduction

Vasomotor symptoms (VMS), such as hot flashes and sweating, are thermoregulatory responses resulting from an inability to maintain the body temperature within a specific range [1]. They are some of the most commonly reported symptoms in postmenopausal women, and disturb women at work, interrupt daily activities, and disrupt sleep [2]. We has recently reported that the presence of VMS is associated with the risk of metabolic syndrome in Korean postmenopausal women [3]. Those findings are in line with the several previous studies reporting the association between VMS and worse metabolic conditions or cardiovascular disease risk factors [4-8]. In contrast, only a few studies have evaluated the relationship between VMS and insulin resistance. Thurston et al. [9] reported the association between hot flashes and insulin resistance by using the homeostatic model assessment (HOMA) index in a US national cohort study. To date, no study has evaluated these associations in the Korean population because of a lack of attention to the significance of such associations.

The aim of this study was to evaluate the association between VMS and insulin resistance, which can be postulated by

fasting glucose level
pausal women.

## Materials and

This cross-sectional study included 2,457 Korean postmenopausal women aged 45 to 65 years who were self-referred for a routine health checkup at the Korea University Anam Hospital (Seoul, Korea) between January 2010 and December

# Dietary Management for the Patient with Insulin Resistance

- Decrease insulin stimulation
  - Dietary modifications which decrease insulin release:
    - Fiber, 10-12 servings of vegetables and low glycemic load fruits
    - ‘Good’ (vs. ‘bad’) fat
    - ‘Good’ (vs. ‘bad’) carbohydrates
    - Protein at every meal
    - Elimination of most inflammatory food: Wheat, dairy, soy, corn, nightshades….
- Modify Gut Microbiota
  - Food first, high fiber
  - Fermented foods
  - Probiotics/prebiotics

# Dietary Management for the Patient with Insulin Resistance

- Increase cellular responsiveness to insulin
  - Agents that modify insulin responsiveness at the cellular level:
    - Spices
    - Herbs
    - Chromium
    - Vitamin D
    - Magnesium
    - Omega-3

ABSTRACT

Alzheimer's disease (AD) constitutes a major socioeconomic challenge due to its disabling features and the rise in prevalence (especially among (peri)menopausal women and type 2 diabetes patients).

The precise etiopathogenesis of AD remains poorly understood. Importantly, its neurodegenerative perspective has been challenged towards a more "systemic" view. Amyloid-β (Aβ) and hyperphosphorylated Tau protein (P-Tau) (the main AD neuropathological features) affect and are affected by peripheral and brain insulin signalling dysfunction, leading to glucose dysme
deficits. This may be anticipated and exacerbated by the p
with insulin) during females' aging, increasing their risk f

Under this perspective, we aimed to discuss the rec
ripheral view of AD, and the role for insulin deficits and
brain. We also focused on the metabolic shift and th
midlife/perimenopause) herein. We finally discussed A
therapeutic potential of restoring brain insulin levels or g
intranasal insulin and use of ketogenic diets.

In sum, AD appears to lie on an intricate crosstalk betw
genetic changes that challenge its traditional view. Hence
gender) and pathophysiological mechanisms will allow
markers and more efficient drugs – all urgent medical n

# Differential effects of estrogen and micronized progesterone or medroxyprogesterone acetate on cognition in postmenopausal women

**Barbara B. Sherwin, Ph.D.** and **Miglena Grigorova, Ph.D.**
Department of Psychology, McGill University, Montreal, Quebec, Canada

## Abstract

**Objective—**To investigate possible differential effects of the coadministration of conjugated equine estrogen (CEE) and a placebo (CEE + PL), CEE and medroxyprogesterone acetate (CEE + MPA), or CEE and micronized P (CEE + MP) on aspects of cognitive functioning in naturally postmenopausal women.

**Design—**Double-blind, randomized, controlled trial.

**Setting—**Gynecologic screening occurred at a university hospital, and neuropsychological testing took place in a university laboratory.

**Patient(s)—**Twenty-four naturally menopausal w
hormone therapy were recruited by means of news

**Intervention(s)—**A battery of mood and neurops
were randomly assigned to receive CEE + PL (n =
The tests were readministered 12 weeks later.

**Main Outcome Measure(s)—**Standardized test
spatial abilities, and visual–spatial sequencing, and

**Result(s)—**Mood improved after treatment in all groups. No changes in scores occurred over time in any cognitive test in the group that received CEE + PL. Only the CEE + MP group had a significant decrease in their delayed verbal memory scores from baseline to after treatment. The CEE + MP-treated women performed significantly better on a test of working memory than women in the other two groups.

**Conclusion(s)—**Coadministration of CEE with MPA or MP caused differential effects on aspects of memory in postmenopausal women. These findings need to be replicated with a larger sample size before their potential clinical implications can be determined.

VIEW POINT

# Alzheimer disease in post-menopausal women: Intervene in the critical window period

*Nayer Jamshed, Fouzia Firdaus Ozair[1], Praveen Aggarwal, Meera Ekka*

Department of Emergency Medicine, All India Institute of Medical Sciences, [1]Department of Forensic Medicine, Hamdard Institute of Medical Sciences and Research, New Delhi, India

**ABSTRACT**

Alzheimer disease (AD) is a crippling neurodegenerative disorder. It is more common in females after menopause. Estrogen probably has a protective role in cognitive decline. Large amount of research has been carried out to see the benefits of hormone replacement therapy with regards to Alzheimer still its neuroprotective effect is not established. Recent studies suggest a reduced risk of AD and improved cognitive functioning of post-menopausal women who used 17 β-est
women yields the maxim
intervention in the critical

**Key Words:** 17 β-estradio

## INTRODUCTION

Alzheimer's disease (AD)
neurodegenerative disease, accou
of all dementia types.[1] Its twice
which could be due to increased l
in brain size.[2] Estrogen has neu
involved in memory and cogn
women are at increased risk tha
Women with Alzheimer have lo
level which lead to the hypothes
neuroprotective. Hormone repl
has been extensively studied in
inconclusive. Recent studies sugge
therapies may provide the most
effect. Early introduction and prolonged therapy preferably for <5 years with 17 β-estradiol prevents AD.

## ROLE OF ESTROGEN THERAPY IN AD

Observational studies have examined both HRT and estrogen replacement therapy (ERT), in relation to AD. ERT was associated with moderately reduced risk for development of AD.[3] An inverse relationship was seen for the duration of ERT and risk for Alzheimer.[4] Increased risk data from the WHIMS demonstrated a higher incidence of dementia and greater cognitive decline among hormone user.[5-7] Hence combination therapies that include progestin may actually ameliorate the beneficial effects of estrogen.[8] Predominant estrogen in premenopausal women is estradiol and its decline is more than estrone in post-menopausal age.
